Let us take a closer look at the essential elements of a symmetric encryption scheme, using <u>Figure 2.2</u>. A source produces a message in plaintext, $X = [X_1, X_2, ..., X_M]$. The M elements of X are letters in some

finite alphabet. Traditionally, the alphabet usually consisted of the 26 capital letters. Nowadays, the binary alphabet $\{0, 1\}$ is typically used. For encryption, a key of the form $K = [K_1, K_2, ..., K_l]$ is generated. If the key is generated at the message source, then it must also be provided to the destination by means of some secure channel. Alternatively, a third party could generate the key and securely deliver it to both source and destination.
